Detail Description Paragraph - DETX (163):

[0202] The K1 type (p42-K) of the p42 antigen was constructed using the Vietnam-Oak Knoll P. falciparum isolate (FVO). There are three parts to this construct: a leader sequence, the p42-K coding region and the histidine tag (FIG. 13). Restriction sites were incorporated into the primers to enable a "sticky-end" ligation of the three fragments. The leader sequence was altered from the original p42-M sequence such that three adenines were added three bases prior to the start site to optimize the codon preference for baculovirus and insect cells as well as the distance between the promoter sequence and the methionine start codon (Ranjan et al. 1995. Virus Genes 9(2):149-153). Primers containing NarI and PstI restriction site sequences were used to amplify the 1,065 base pair p42-K coding region corresponding to the Ala.sub.1349 to Ser.sub.1723 (as numbered by Miller et al. 1993. Mol. Biochem. Parasitol 59(1):1-14.) of MSP-1 from genomic P. falciparum DNA. Primers containing BamHI and NarI restriction site sequences were used to amplify the 91 base pair leader sequence. Oligonucleotides containing PstI and KpnI

restriction site sequences were made to generate the 25 base pair histidine tag. All primers and oligonucleotide sequences used for the p42-K constructs are shown in Table 1.

ABSTRACT:

The present invention provides isolated nucleic acids encoding human SCA2 protein, or fragments thereof, and isolated SCA2 proteins encoded thereby. Further provided are vectors containing invention nucleic acids, probes that hybridize thereto, host cells transformed therewith, antisense oligonucleotides thereto and compositions containing antibodies that specifically bind to invention polypeptides, as well as transgenic non-human mammals that express the invention protein. In addition, methods for diagnosing spinocerebellar Ataxia Type 2 are provided.

Detail Description Paragraph - DETX (23):

[0043] Vectors that contain both a promoter and a cloning site into which a polynucleotide can be operatively linked are well known in the art. Such vectors are capable of transcribing RNA in vitro or in vivo, and are commercially available from sources such as Stratagene (La Jolla, Calif.) and Promega Biotech (Madison, Wis.). In order to optimize expression and/or in vitro transcription, it may be necessary to remove, add or alter 5' and/or 3' untranslated portions of the clones to eliminate extra, potential inappropriate alternative translation initiation codons or other sequences that may interfere with or reduce expression, either at the level of transcription or translation. Alternatively, consensus ribosome binding sites can be inserted immediately 5' of the start codon to enhance expression. (See, for example, Kozak, J. Biol. Chem. 266:19867 (1991)). Similarly, alternative codons, encoding the same amino acid, can be substituted for coding sequences of the SCA2 polypeptide in order to enhance transcription (e.g., the codon preference of the host cell can be adopted, the presence of G-C rich domains can be reduced, and the like).

ABSTRACT:

Methods and pharmaceutical compositions for administering protein or gene therapy to tissues or organs having an epithelial cell layer are provided. A protein or nucleic acid encoding the protein is administered to the target tissue or organ in combination with treatment with a delivery enhancing agent which increases the delivery of the interferon or nucleic acid to the cells of the target tissues or organs. The methods and combinations are particularly useful in the treatment of cancers and other conditions responsive to interferon therapy. An exemplary method comprises the transurethral intravesical administration to the bladder of a therapeutically effective amount of a pharmaceutical composition comprising an alpha-interferon or a gene delivery system encoding the interferon and SYN3 or a SYN3 homolog or analog. In the urinary bladder, as much as a 10 to 1000 fold increased in interferon levels and activity may be observed with the use of a SYN3 formulation as opposed to a PBS formulation of the same interferon protein or interferon gene delivery system.

Detail Description Paragraph - DETX (14):

[0037] The term "gene" as used herein is intended to refer to a nucleic acid sequence which encodes an polypeptide. This definition includes various sequence polymorphisms, mutations, and/or sequence variants wherein such alterations do not affect the function of the gene product. The term "gene" may include not only coding sequences but also regulatory regions such as promoters, enhancers, and termination regions. The term further can include all introns and other DNA sequences spliced from the mRNA transcript, along with variants resulting from alternative splice sites. Nucleic acid sequences encoding the polypeptide can be DNA or RNA which directs the expression of a specific protein or peptide. These nucleic acid sequences may be a DNA strand sequence that is transcribed into RNA or an RNA sequence that is translated into protein. The nucleic acid sequences include both the full-length nucleic acid sequences as well as non-full length sequences derived from the full-length protein. It is further understood that the sequence includes the degenerate codons of the native sequence or sequences that may be introduced to provide codon preference in a specific host cell.

ABSTRACT:

The invention provides compositions and methods related to human telomerase reverse transcriptase (hTRT), the catalytic protein subunit of human telomerase. The polynucleotides and polypeptides of the invention are useful for diagnosis, prognosis and treatment of human diseases, for changing the proliferative capacity of cells and organisms, and for identification and screening of compounds and treatments useful for treatment of diseases such as cancers.

[0001] This application is a continuation-in-part of U.S. application Ser. No. 09/843,676, filed Apr. 26, 2001, and a continuation-in part of U.S. application Ser. No. 10/044,692, filed Jan. 11, 2002, and a continuation of U.S. patent application Ser. No. 09/432,503, filed Nov. 2, 1999, which is a continuation of U.S. patent application Ser. No. 08/974,549 filed Nov. 19, 1997, U.S. Pat. No. 6,166,178, which is a continuation-in-part application of

U.S. patent application Ser. No. 08/915,503, filed Aug. 14, 1997, abandoned, and a continuation-in-part application of U.S. patent application Ser. No. 08/912,951, filed Aug. 14, 1997, U.S. Pat. No. 6,475,789 and a continuation-in-part of application of U.S. patent application Ser. No. 08/911,312, filed Aug. 14, 1997, abandoned, all three of which are continuations-in-part of U.S. patent application Ser. No. 08/854,050, filed May 9, 1997, U.S. Pat. No. 6,261,836, which is a continuation-in-part of U.S. patent application Ser. No. 08/851,843, filed May 6, 1997, U.S. Pat. No. 6,093,809, which is a continuation-in-part of U.S. patent application Ser. No. 08/846,017, filed Apr. 25, 1997, abandoned, which is a continuation-in-part of U.S. application Ser. No. 08/844,419 filed Apr. 18, 1997, abandoned. This application also claims priority to Patent Convention Treaty Patent Application Serial No.: PCT/US97/17885 (published on Apr. 9, 1998 as WO 98/14593) and to Patent Convention Treaty Patent Application Serial No.: PCT/US97/17618 (published on Apr. 9, 1998 as WO 98/14592), both designating the U.S. and filed in the U.S. Receiving Office on Oct. 1, 1997. Each of the aforementioned applications is explicitly incorporated herein by reference in its entirety and for all purposes. This application also incorporates by reference copending U.S. patent application Ser. No. 08/974,584, filed Nov. 19, 1997, in its entirety and for all purposes.

---------- KWIC ---------

Detail Description Paragraph - DETX (68):

[0184] The present invention further provides altered or modified hTRT nucleic acids. It will be recognized by one of skill that the cloned or amplified hTRT nucleic acids obtained can be modified (e.g., truncated, derivatized, altered) by methods well known in the art (e.g., site-directed mutagenesis, linker scanning mutagenesis) or simply synthesized de novo as described below. The altered or modified hTRT nucleic acids are useful for a variety of applications, including, but not limited to, facilitating cloning or manipulation of an hTRT gene or gene product, or expressing a variant hTRT gene product. For example, in one embodiment, the hTRT gene sequence is altered such that it encodes an hTRT polypeptide with altered properties or activities, as discussed in detail in infra, for example, by mutation in a conserved motif of hTRT. In another illustrative example, the mutations in the protein coding region of an hTRT nucleic acid may be introduced to alter glycosylation patterns, to change codon preference, to produce splice variants, remove protease-sensitive sites, create antigenic domains, modify specific activity, and the like. In other embodiments, the nucleotide sequence encoding hTRT and its derivatives is changed without altering the encoded amino acid sequences, for example, the production of RNA transcripts having more desirable properties, such as increased translation efficiency or a greater or a shorter half-life, compared to transcripts produced from the naturally occurring sequence. In yet another embodiment, altered codons are selected to increase the rate at which expression of the peptide occurs in a particular prokaryotic or eukaryotic expression host in accordance with the frequency with which particular codons are utilized by the host. Useful in vitro and in vivo recombinant techniques that can be used to prepare variant hTRT polynucleotides of the invention are found in Sambrook et al. and Ausubel et al., both supra.

Detail Description Paragraph - DETX (97):

[0115] The polynucleotide sequences of the present invention can be engineered in order to alter a .beta.-secretase coding sequence for a variety of reasons, including but not limited to, alterations that modify the cloning, processing and/or expression of the gene product. For example, alterations may be introduced using techniques which are well known in the art, e.g., site-directed mutagenesis, to insert new restriction sites, to alter glycosylation patterns, to change codon preference, to produce splice variants, etc. For example, it may be advantageous to produce .beta.-secretase-encoding nucleotide sequences possessing non-naturally occurring codons. Codons preferred by a particular prokaryotic or eukaryotic host (Murray, E. et al., (1989) Nuc. Acids Res. 17:477-508) can be selected, for example, to increase the rate of .beta.-secretase polypeptide expression or to produce recombinant RNA transcripts having desirable properties, such as a longer half-life, than

transcripts produced from naturally occurring sequence. This may be particularly useful in producing recombinant enzyme in non-mammalian cells, such as bacterial, yeast, or insect cells. The present invention also includes recombinant constructs comprising one or more of the sequences as broadly described above. The constructs comprise a vector, such as a plasmid or viral vector, into which a sequence of the invention has been inserted, in a forward or reverse orientation. In a preferred aspect of this embodiment, the construct further comprises regulatory sequences, including, for example, a promoter, operably linked to the sequence. Large numbers of suitable vectors and promoters are known to those of skill in the art, and are commercially available. Appropriate cloning and expression vectors for use with prokaryotic and eukaryotic hosts are also described in Sambrook, et al., (supra).

ABSTRACT:

The invention provides compositions and methods related to human telomerase reverse transcriptase (hTRT), the catalytic protein subunit of human telomerase. The polynucleotides and polypeptides of the invention are useful for diagnosis, prognosis and treatment of human diseases, for changing the proliferative capacity of cells and organisms, and for identification and screening of compounds and treatments useful for treatment of diseases such as cancers.

Detail Description Paragraph - DETX (61):

[0177] The present invention further provides altered or modified hTRT nucleic acids. It will be recognized by one of skill that the cloned or amplified hTRT nucleic acids obtained can be modified (e.g., truncated, derivatized, altered) by methods well known in the art (e.g., site-directed mutagenesis, linker scanning mutagenesis) or simply synthesized de novo as described below. The altered or modified hTRT nucleic acids are useful for a variety of applications, including, but not limited to, facilitating cloning or manipulation of an hTRT gene or gene product, or expressing a variant hTRT gene product. For example, in one embodiment, the hTRT gene sequence is altered such that it encodes an hTRT polypeptide with altered properties or activities, as discussed in detail in infra, for example, by mutation in a conserved motif of hTRT. In another illustrative example, the mutations in the protein coding region of an hTRT nucleic acid may be introduced to alter glycosylation patterns, to change codon preference, to produce splice variants, remove protease-sensitive sites, create antigenic domains, modify specific activity, and the like. In other embodiments, the nucleotide sequence encoding hTRT and its derivatives is changed without altering the encoded amino acid sequences, for example, the production of RNA transcripts having more desirable properties, such as increased translation efficiency or a greater or a shorter half-life, compared to transcripts produced from the naturally occurring sequence. In yet another embodiment, altered codons are selected to increase the rate at which expression of the peptide occurs in a particular prokaryotic or eukaryotic expression host in accordance with the frequency with which particular codons are utilized by the host. Useful in vitro and in vivo recombinant techniques that can be used to prepare variant hTRT polynucleotides of the invention are found in Sambrook et al. and Ausubel et al., both supra.

ABSTRACT:

The present invention outlines a novel approach to utilizing the results of genomic sequence information by computer-directed polynucleotide assembly based upon information available in databases such as the human genome database. Specifically, the present invention may be used to select, synthesize and assemble a novel, synthetic target polynucleotide sequence encoding a target polypeptide. The target polynucleotide may encode a target polypeptide that exhibits enhanced or altered biological activity as compared to a model polypeptide encoded by a natural (wild-type) or model polynucleotide sequence.

---------- KWIC ---------

Detail Description Paragraph - DETX (161):
[0195] In addition to the above codon preferences, specific promoter, enhancer, replication or drug resistance sequences can be included in a synthetic nucleic acid sequence of the invention. The length of the construction can be adjusted by padding to give a round number of bases based on about 25 to 100 bp synthesis. The synthesis of sequences of about 25 to 100 bp in length can be manufactured and assembled using the array synthesizer system and may be used without further purification. For example, two 96-well plates containing 100-mers could give a 9600 bp construction of a target sequence.

ABSTRACT:

Compositions and methods for controlling plant pests are disclosed. In particular, novel nucleic acid sequences encoding modified Cry3A toxins having increased toxicity to corn rootworm are provided. By inserting a protease recognition site such as cathepsin G, that is recognized by a gut protease of a target insect in at least one position of a Cry3A toxin a modified Cry3A toxin having significantly greater toxicity, particularly to western and northern corn rootworm is designed. Further, a method of making the modified Cry3A toxins and methods of using the modified Cry3A nucleic acid sequences, for example in microorganisms to control insects or in transgenic plants to confer protection from insect damage, and a method of using the modified Cry3A toxins, and compositions and formulations comprising the modified Cry3A toxins, for example applying the modified Cry3A toxins or compositions or formulations to insect-infested areas, or to prophylactically treat insect-susceptible areas or plants to confer protection against the insect pests are disclosed.

---------- KWIC ---------

Summary of Invention Paragraph - BSTX (137):
[0137] In a particularly preferred embodiment, at least one of the insecticidal modified Cry3A toxins of the invention is expressed in a higher

organism, e.g., a plant. In this case, transgenic plants expressing effective amounts of the modified Cry3A toxins protect themselves from insect pests. When the insect starts feeding on such a transgenic plant, it also ingests the expressed modified Cry3A toxins. This will deter the insect from further biting into the plant tissue or may even harm or kill the insect. A nucleotide sequence of the present invention is inserted into an expression cassette, which is then preferably stably integrated in the genome of said plant. In another preferred embodiment, the nucleotide sequence is included in a non-pathogenic self-replicating virus. Plants transformed in accordance with the present invention may be monocots or dicots and include, but are not limited to, maize, wheat, barley, rye, sweet potato, bean, pea, chicory, lettuce, cabbage, cauliflower, broccoli, turnip, radish, spinach, asparagus, onion, garlic, pepper, celery, squash, pumpkin, hemp, zucchini, apple, pear, quince, melon, plum, cherry, peach, nectarine, apricot, strawberry, grape, raspberry, blackberry, pineapple, avocado, papaya, mango, banana, soybean, tomato, sorghum, sugarcane, sugar beet, sunflower, rapeseed, clover, tobacco, carrot, cotton, alfalfa, rice, potato, eggplant, cucumber, Arabidopsis, and woody plants such as coniferous and deciduous trees. Once a desired nucleotide sequence has been transformed into a particular plant species, it may be propagated in that species or moved into other varieties of the same species, particularly including commercial varieties, using traditional breeding techniques. A nucleotide sequence of this invention is preferably expressed in transgenic plants, thus causing the biosynthesis of the corresponding modified Cry3A toxin in the transgenic plants. In this way, transgenic plants with enhanced resistance to insects are generated. For their expression in transgenic plants, the nucleotide sequences of the invention may require other modifications and optimization. Although in many cases genes from microbial organisms can be expressed in plants at high levels without modification, low expression in transgenic plants may result from microbial nucleotide sequences having codons that are not preferred in plants. It is known in the art that all organisms have specific preferences for codon usage, and the codons of the nucleotide sequences described in this invention can be changed to conform with plant preferences, while maintaining the amino acids encoded thereby. Furthermore, high expression in plants is best achieved from coding sequences that have at least about 35% GC content, preferably more than about 45%, more preferably more than about 50%, and most preferably more than about 60%. Microbial nucleotide sequences that have low GC contents may express poorly in plants due to the existence of ATTTA motifs that may destabilize messages, and AATAAA motifs that may cause inappropriate polyadenylation. Although preferred gene sequences may be adequately expressed in both monocotyledonous and dicotyledonous plant species, sequences can be modified to account for the specific codon preferences and GC content preferences of monocotyledons or dicotyledons as these preferences have been shown to differ (Murray et al. Nucl. Acids Res. 17:477-498 (1989)). In addition, the nucleotide sequences are screened for the existence of illegitimate splice sites that may cause message truncation. All changes required to be made within the nucleotide sequences such as those described above are made using well known techniques of site directed mutagenesis, PCR, and synthetic gene construction using the methods described in the published patent applications EP 0 385 962 (to Monsanto), EP 0 359 472 (to Lubrizol, and WO 93/07278 (to Ciba-Geigy).

ABSTRACT:

The present invention provides a dual expression vector, and methods for its use, for the expression and secretion of a full-length polypeptide of interest in eukaryotic cells, and a soluble domain or fragment of the polypeptide in bacteria. When expressed in bacteria, transcription from a bacterial promoter within a first intron and termination at the stop codon in a second intron results in expression of a fragment of the polypeptide, e.g., a Fab fragment, whereas in mammalian cells, splicing removes the bacterial regulatory sequences located in the two introns and generates the mammalian signal sequence, allowing expression of the full-length polypeptide, e.g., IgG heavy or light chain polypeptide. The dual expression vector system of the invention can be used to select and screen for new monoclonal antibodies, as well as to optimize monoclonal antibodies for binding to antigenic molecules of interest.

[0001] This application claims the benefit of priority under 35 U.S.C. .sctn. 119(e) to provisional application No. 60/439,492, filed Jan. 9, 2003, which is incorporated by reference herein in its entirety.

Detail Description Paragraph - DETX (60):

[0097] Vectors that contain both a promoter and a cloning site into which a polynucleotide can be operatively linked are well known in the art. Such vectors are capable of transcribing RNA in vitro or in vivo, and are commercially available from sources such as Stratagene (La Jolla, Calif.) and Promega Biotech (Madison, Wis.). In order to optimize expression and/or in vitro transcription, it may be necessary to remove, add or alter 5' and/or 3' untranslated portions of the cloned DNA to eliminate extra, potential

inappropriate alternative translation initiation codons or other sequences that may interfere with or reduce expression, either at the level of transcription or translation. Alternatively, consensus ribosome binding sites can be inserted immediately 5' of the start codon to enhance expression (see, e.g., Kozak, 1991, J. Biol. Chem. 266:19867). Similarly, alternative codons, encoding the same amino acid, can be substituted for coding sequences in order to enhance translation (e.g., the codon preference of the host cell can be adopted, the presence of G-C rich domains can be reduced, and the like).

Detailed Description Text - DETX (108):
The nucleotide sequence of the original BVp42 construct was modified to optimize for insect cell line (High Five, Trichoplusia ni) codon preferences, distance between the promoter sequence and translation initiation codon, and preferred nucleotide composition of the sequences immediately before the initiation codon. The modified construct has been designated BVp42-M and the nucleotide sequence of this construct is shown in FIG. 12.

Detailed Description Text - DETX (111):
The K1 type (p42-K) of the p42 antigen was constructed using the Vietnam-Oak Knoll P. falciparum isolate (FVO). There are three parts to this construct: a leader sequence, the p42-K coding region and the histidine tag (FIG. 13). Restriction sites were incorporated into the primers to enable a "sticky-end" ligation of the three fragments. The leader sequence was altered from the original p42-M sequence such that three adenines were added three bases prior to the start site to optimize the codon preference for baculovirus and insect cells as well as the distance between the promoter sequence and the methionine

start codon (Ranjan et al 1995. Virus Genes 9(2):149-153). Primers containing NarI and PstI restriction site sequences were used to amplify the 1,065 base pair p42-K coding region corresponding to the Ala.sub.1349 to Ser.sub.1723 (as numbered by Miller et at 1993. Mol. Biochem. Parasitol 59(1):1-14.) of MSP- 1 from genomic P. falciparum DNA. Primers containing BamHI and NarI restriction site sequences were used to amplify the 91 base pair leader sequence. Oligonucleotides containing PstI and KpnI restriction site sequences were made to generate the 25 base pair histidine tag. All primers and oligonucleotide sequences used for the p42-K constructs are shown in Table 1.

This application is a Divisional application based on Ser. No. 08/935,105, filed Sep. 29, 1997, now U.S. Pat. No. 6,376,660 which is a Divisional of Ser. No. 08/231,193, filed Apr. 20, 1994, now U.S. Pat. No. 5,849,895, which is a continuation-in-part of U.S. Ser. No. 08/052,449, filed Apr. 20, 1993, now abandoned.

US-CL-CURRENT: 530/350, 435/69.1 , 435/7.21 , 436/501 , 536/23.5

ABSTRACT:

In accordance with the present invention, there are provided nucleic acids encoding human NMDA receptor protein subunits and the proteins encoded thereby. The NMDA receptor subunits of the invention comprise components of NMDA receptors that have cation-selective channels and bind glutamate and NMDA. In one aspect of the invention, the nucleic acids encode NMDAR1 and NMDAR2 subunits of human NMDA receptors. In a preferred embodiment, the invention nucleic acids encode NMDAR1, NMDAR2A, NMDAR2B, NMDAR2C and NMDAR2D subunits of human NMDA receptors. In addition to being useful for the production of NMDA receptor subunit proteins, these nucleic acids are also useful as probes, thus enabling those skilled in the art, without undue experimentation, to identify and isolate related human receptor subunits. Functional glutamate receptors can be assembled, in accordance with the present invention, from a plurality of one type of NMDA receptor subunit protein (homomeric) or from a mixture of two or more types of subunit proteins (heteromeric). In addition to disclosing novel NMDA receptor protein subunits, the present invention also comprises methods for using such receptor subunits to identify and characterize compounds which affect the function of such receptors, e.g., agonists, antagonists, and modulators of glutamate receptor function. The invention also comprises methods for determining whether unknown protein(s) are functional as NMDA receptor subunits.

---------- KWIC ---------

Detailed Description Text - DETX (48):

As used herein, the term "operatively linked" refers to the functional relationship of DNA with regulatory and effector sequences of nucleotides, such as promoters, enhancers, transcriptional and translational stop sites, and other signal sequences. For example, operative linkage of DNA to a promoter refers to the physical and functional relationship between the DNA and the promoter such that the transcription of such DNA is initiated from the promoter by an RNA polymerase that specifically recognizes and binds to the promoter, and transcribes the DNA. In order to optimize expression and/or in vitro transcription, it may be necessary to remove, add or alter 5' and/or 3' untranslated portions of the clones to eliminate extra, potential inappropriate alternative translation initiation (i.e., start) codons or other sequences that may interfere with or reduce expression, either at the level of transcription or translation. Alternatively, consensus ribosome binding sites (see, for example, Kozak (1991) J. Biol. Chem. 266:19867-19870) can be inserted immediately 5' of the start codon and may enhance expression. Likewise, alternative codons, encoding the same amino acid, can be substituted for coding sequences of the NMDAR subunits in order to enhance transcription (e.g., the codon preference of the host cells can be adopted, the presence of G-C rich domains can be reduced, and the like). Furthermore, for potentially enhanced expression of NMDA receptor subunits in amphibian oocytes, the subunit coding sequence can optionally be incorporated into an expression construct wherein the 5'- and 3'-ends of the coding sequence are contiguous with Xenopus .beta.-globin gene 5' and 3' untranslated sequences, respectively. For example, NMDA receptor subunit coding sequences can be incorporated into vector pSP64T (see Krieg and Melton (1984) in Nucleic Acids Research 12:7057-7070), a modified form of pSP64 (available from Promega, Madison, Wis.). The coding sequence is inserted between the 5' end of the .beta.-globin gene and the 3' untranslated sequences located downstream of the SP6 promoter. In vitro transcripts can then be generated from the resulting vector. The desirability of (or need for) such modification may be empirically determined.
